TEAM LEAD VERSION (DevOps-Week-1)

Meeting Agenda

- ► Icebreaking
- ► Microlearning
- **▶** Questions
- ► Interview/Certification Questions
- ► Coding Challenge
- ► Video of the week
- ► Retro meeting
- ► Case study / project

Teamwork Schedule

Ice-breaking 5m

• Personal Questions (Stay at home & Corona, Study Environment, Kids etc.)

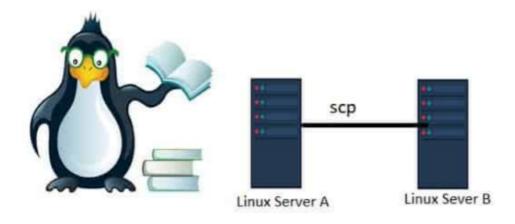

- Any challenges (Classes, Coding, AWS, studying, etc.)
- Ask how they're studying, give personal advice.
- Remind that practice makes perfect.

Team work 10m

• Ask what exactly each student does for the team, if they know each other, if they care for each other, if they follow and talk with each other etc.

Microlearning 15m

How to Use SCP Command

SCP (**secure copy**) is a command-line utility that allows you to securely copy files and directories between two locations. SCP uses by default the port 22, and connect via an encrypted connection or secure shell connection (ssh).

With scp, you can copy a file or directory:

- From your local system to a remote system.
- From a remote system to your local system.
- Between two remote systems from your local system.

When transferring data with scp, both the files and password are encrypted so that anyone snooping on the traffic doesn't get anything sensitive.

SCP Command Syntax:

The scp command syntax take the following form:

```
scp [OPTION] [user@]SRC_HOST:]file1 [user@]DEST_HOST:]file2
```

OPTION: scp options such as cipher, ssh configuration, ssh port, limit, recursive copy ...etc.

```
[user@]SRC_HOST:]file1: Source file.

[user@]DEST_HOST:]file2: Destination file.
```

Local files should be specified using an absolute or relative path, while remote file names should include a user and host specification.

scp provides a number of options that control every aspect of its behavior. The most widely used options are:

- -P: Specifies the remote host ssh port.
- -p: Preserves files modification and access times.
- -q: Use this option if you want to suppress the progress meter and non-error messages.
- -C: This option forces scp to compresses the data as it is sent to the destination machine.
- -r: This option tells scp to copy directories recursively.

The colon (:) is how scp distinguish between local and remote locations.

To be able to copy files, you must have at least read permissions on the source file and write permission on the target system.

1. Copy a Local File to a Remote System with the scp Command:

To copy a file from a local to a remote system run the following command:

```
scp file.txt remote_username@10.10.0.2:/remote/directory
```

file.txt is the name of the file we want to copy, remote_username is the user on the remote server, 10.10.0.2 is the server IP address. The /remote/directory is the path to the directory you want to copy the file to.

If you don't specify a remote directory, the file will be copied to the remote user home directory.

You will be prompted to enter the user password, and the transfer process will start.

Omitting the filename from the destination location copies the file with the original name. If you want to save the file under a different name, you need to specify the new file name:

```
scp file.txt remote_username@10.10.0.2:/remote/directory/newfilename.txt
```

If SSH on the remote host is listening on a port other than the default 22 then you can specify the port using the -P argument:

```
scp -P 2322 file.txt remote_username@10.10.0.2:/remote/directory
```

The command to copy a directory is much like as when copying files. The only difference is that you need to use the -r flag for recursive.

To copy a directory from a local to remote system, use the -r option:

```
scp -r /local/directory remote_username@10.10.0.2:/remote/directory
```

• if you use pem key, you need the add it;

```
scp tyler.pem file.txt remote_username@10.10.0.2:/remote/directory
```

2. Copy a Remote File to a Local System using the scp Command:

To copy a file from a remote to a local system, use the remote location as a source and local location as the destination.

For example to copy a file named **file.txt** from a remote server with IP 10.10.0.2 run the following command:

```
scp remote_username@10.10.0.2:/remote/file.txt /local/directory
```

If you haven't set a passwordless SSH login to the remote machine, you will be asked to enter the user password.

3. Copy a File Between Two Remote Systems using the scp Command:

When using scp you don't have to log in to one of the servers to transfer files from one to another remote machine.

The following command will copy the file /files/file.txt from the remote host host1.com to the directory /files on the remote host host2.com.

```
scp user1@host1.com:/files/file.txt user2@host2.com:/files
```

You will be prompted to enter the passwords for both remote accounts.

To route the traffic through the machine on which the command is issued, use the -3 option:

scp -3 user1@host1.com:/files/file.txt user2@host2.com:/files

Ask Questions 15m

1. How can we rename a branch? (git)

- A. git checkout -b current-branch-name new-branch-name
- **B.** git branch checkout current-branch-name new-branch-name
- **C.** git branch -m current-branch-name new-branch-name
- **D.** git clone current-branch-name new-branch-name

Answer: C

2. Which Linux command gives the number of lines, words and characters in the data?

- A. cat
- B. wc
- C. tree
- **D.** tr

Answer: B

3. What is boto3 used for?

- A. It is used to communicate with a database.
- B. It enables you to create, update, and delete AWS resources with your Python scripts.
- **C.** It lets you deploy containers to clusters, meaning a network of virtual machines.
- **D.** It helps automate the parts of software development related to building, testing, and deploying, facilitating continuous integration and continuous delivery.

Answer: B

4. Which command is used to terminate the Terraform-managed infrastructure?

- A. terraform terminate
- **B.** terraform erase
- C. terraform delete
- **D.** terraform destroy

Answer: D

5. Which command is used to list of the resources in state in Terraform?

- A. terraform state --list
- B. terraform show list
- C. terraform state list
- **D.** terraform Is state

Answer: C

Interview/Certification Questions

20m

1. What are the different phases in DevOps?

The various phases of the DevOps lifecycle are as follows:

Plan: Initially, there should be a plan for the type of application that needs to be developed. Getting a rough picture of the development process is always a good idea.

Code: The application is coded as per the end-user requirements.

Build: Build the application by integrating various codes formed in the previous steps.

Test: This is the most crucial step of the application development. Test the application and rebuild, if necessary.

Integrate: Multiple codes from different programmers are integrated into one.

Deploy: Code is deployed into a cloud environment for further usage. It is ensured that any new changes do not affect the functioning of a high traffic website.

Operate: Operations are performed on the code if required. Monitor - Application performance is monitored. Changes are made to meet the end-user requirements.

2. Explain the concept behind Infrastructure as Code (IaC).

Answer:

Infrastructure as Code (IaC) is a process for managing and operating data servers, storage systems, system configurations, and network infrastructure.

In traditional configuration management practices, each minute configuration change required manual action by system administrators and the IT support team. But with IaC, all the configuration details are managed and stored in a standardized file system, wherein the system automatically manages infrastructure changes and deals with system configurations.

Therefore, we do not require most of the manual effort since everything is managed and automated by following the IaC approach. Tools such as Terraform or Ansible can be used to implement IaC approach.

3. How Terraform works?

Answer:

Terraform produce an execution plan delineate, what it will do to reach the desired state, and then executes it to build the described infrastructure. As the configuration changes, Terraform is able to determine what changed and create incremental execution plans which can be applied.

4. You have an EC2 instance in the AWS us-east-1 region. The application in the instance needs to access a DynamoDB table that is located in the AWS us-east-2 region. The connection must be private without leaving the Amazon network and the instance should not use any public IP for communication. How would you configure this?

- **A.** Configure an inter-region VPC endpoint for the DynamoDB service.
- **B.** Configure inter-region VPC peering and create a VPC endpoint for DynamoDB in us-east-2.
- **C.** Create an inter-region VPC peering connection between us-east-1 and us-east2.
- **D.** There is no way to setup the private inter-region connections.

Answer: B

For the private connections between regions, VPC peering should be used. Then VPC endpoint allows users to privately access the DynamoDB service. Please check the reference in Link

Option A is incorrect: Because you cannot configure an inter-region VPC endpoint directly.

Option B is CORRECT: With inter-region VPC peering and VPC endpoint (PrivateLink), the EC2 instance can

communicate with the DynamoDB table privately even if they belong to different regions.

Option C is incorrect: This option does not mention the usage of VPC endpoint.

Option D is incorrect: Because VPC peering supports the inter-region connections.

- 5. You own a MySQL RDS instance in AWS Region us-east-1. The instance has a Multi-AZ instance in another availability zone for high availability. As business grows, there are more and more clients coming from Europe (eu-west-2) and most of the database workload is read-only. What is the proper way to reduce the load on the source RDS instance?
- **A.** Create a snapshot of the instance and launch a new instance in eu-west-2.
- **B.** Promote the Multi-AZ instance to be a Read Replica and move the instance to eu-west-2 region.
- **C.** Configure a read-only Multi-AZ instance in eu-west-2 as Read Replicas cannot span across regions.
- **D.** Create a Read Replica in the AWS Region eu-west-2.

Answer: *D*

Read Replica should be used to share the read workload of the source DB instance. Read Replica can also be configured in a different AWS region. Refer to Link

Option A is incorrect: Because Read Replica should be configured to share the read traffic. You should not launch a totally new instance.

Option B is incorrect: Because a Multi-AZ instance cannot be promoted to be a Read Replica.

Option C is incorrect: Because a Read Replica can be launched in another region for RDS MySQL.

*Option D is CORRECT: Users can quickly configure a Read Replica in another region.

Video of the Week 10m

• Terraform Explained

Retro Meeting on a personal and team level

10m

Ask the questions below:

- What went well?
- What could be improved?
- What will we commit to do better in the next week?

Coding Challenge

5m

• Coding Challenge: Reverse the Numbers

Case study/Project

10m

• There is no project for this week.

Closing

5m

- -Next week's plan
- -QA Session
